LAB7 - IPTables

For outgoing traffic (from 10.20.111.0/24 to 10.10.111.0/24) - your internal machine should be able to communicate with the external network and the external machines without restrictions.

The screenshot shows the stateful rule being appended to the FORWARD chain that allows all the traffic to go from the 10.20.111.0/24 incoming at eth1 and outgoing at eth0.

iptables -A OUTPUT -s 10.10.111.0/24 -o eth0 -m state --state NEW,ESTABLISHED -j ACCEPT

```
router:~# iptables -A OUTPUT -s 10.20.111.0/24 -o eth0 -m state --state NEW,ESTABLISHED -j ACCEPT
router:~# iptables -L
Chain INPUT (policy ACCEPT)
target     prot opt source                destination

Chain FORWARD (policy ACCEPT)
target     prot opt source                destination

Chain OUTPUT (policy ACCEPT)
target     prot opt source                destination
ACCEPT     all  --  10.20.111.0/24        anywhere             state NEW,ESTABLISHED
router:~# _
```

Part A

1. The internal machines should respond to a ping from 10.10.111.0/24

The entries made were verified by using the iptables -L command

```
router:~# iptables -A INPUT -i eth0 -p icmp --icmp-type echo-reply -s 10.10.111.0/24 -m state --state NEW,ESTABLISHED -j ACCEPT
router:~# iptables -L
Chain INPUT (policy ACCEPT)
target     prot opt source                destination
ACCEPT     icmp --  10.10.111.0/24        anywhere             icmp echo-reply state NEW,ESTABLISHED

Chain FORWARD (policy ACCEPT)
target     prot opt source                destination

Chain OUTPUT (policy ACCEPT)
target     prot opt source                destination
ACCEPT     all  --  10.10.111.0/24        anywhere             state NEW,ESTABLISHED
router:~# _
```

Ping from windows machine.

Part B

Flushing all the rules from the iptables by using the following commands.

iptables -F

iptables -t nat -F

I ran the command "iptables -t nat -L -nv" to make sure that there were not any previous set rules.

```
router:~#
router:~# iptables -F
router:~# iptables -t nat -F
router:~# iptables -t nat -L -nv
Chain PREROUTING (policy ACCEPT 35 packets, 4844 bytes)
  pkts bytes target    prot opt in     out     source destination
Chain POSTROUTING (policy ACCEPT 4 packets, 228 bytes)
  pkts bytes target    prot opt in     out     source destination
Chain OUTPUT (policy ACCEPT 2 packets, 142 bytes)
  pkts bytes target    prot opt in     out     source destination
router:~# _
```

We translate traffic from the internal machine with source IP address 10.20.111.2 to a source ip address of 10.10.111.x (it is the address of the outside interface of the firewall).

iptables -t nat -A POSTROUTING -o eth0 -j MASQUERADE

where -t nat : allows to alter NAT table of iptables

POSTROUTING: address translation occurs before routing.

MASQUERADE: used to do source network translation

```
Connected (unencrypted) to: Xen-Int-rtt_new_base144
router:~# iptables -t nat -A POSTROUTING -o eth0 -j MASQUERADE
router:~# iptables -L -t nat -nv
Chain PREROUTING (policy ACCEPT 190 packets, 19022 bytes)

```

Part C

1) Iptables can be used as a packet filtering tool. A privileged user can define certain rules applicable to the incoming and outgoing packets to and from the system. In addition, it can also perform network address and port translation and packet mangling.

It can work either as a host based firewall or a network based firewall depending on whether it is looking at the packets that are going to and from the host or being routed through the network.

The rules in iptables are grouped together into chains. A chain is a set of rules that determines the action to be taken on a packet.

Each rule in a chain consists of the specification of the packets those will match with it. As a packet traverse a chain, it is checked against each rule sequentially. If a rule matches a packet then corresponding action is taken on the packet. Once a matching rule is found for a packet, it is further not checked with the other rules coming after the current matched rule. If none of the existing rule matches the packet, then it is processed according to the default rule set.

A table in turn is formed from the chains. It has different types of table - filter, NAT, mangle, raw. The different types of chains in iptables are - INPUT, OUTPUT and FORWARD. If a packet is entering a host with iptables firewall, the rule goes to INPUT chain. If a packet is leaving a host with iptables firewall, the rule goes to OUTPUT chain. Also, if a packet is going through the firewall, the rule goes to forward chain.

2) INPUT chain - This applies for all the packets which are destined to the host with iptables.

OUTPUT chain - This applies for all the packets that are leaving the host with iptables.

FORWARD chain - This applies for all the packets going through the firewall. It is for the packets that are neither emitted by the host nor directed to the host.

3) Deny - The packet is discarded, dropped to the floor, assigned to oblivion. No reply packet of any kind is sent. There is no response to the SYN packet. If a rule is set which matches a particular source address with DENY, then the system is seen as down to the source address. But, if we set DENY for some port ranges, then it allows the source address to know that we are running a firewall.

Reject - An ICMP port unreachable packet is sent to the source address. This tells the remote host that the system is up and running with a firewall.

Accept - When a service is not listening on a port number, the response to the SYN packet (S) from a source address is a connection reset (R). When a service is listening on a port number, a successful TCP connection is established.

4) Some alternative network based firewalls

i) Firewall-1: It is one of the most powerful commercial firewall.

Pros: Good documentation, Professional support, Training services available, includes high-end features such as load balancing and redundancy, excellent reputation

Cons: Requires intensive training for the administrator, very expensive

ii) PfSense: PfSense is BSD based firewall. It is slightly more secure than a firewall using Iptables would be, because it makes a connection harder to spoof by tracking TCP sequence numbers.

iii) Smoothwall Advanced: It is used as an open source firewall. It is designed to be used as a corporate office firewall, with the options to create authentication-based access to different parts of the network and its web proxy and email filtering systems.

Cons: Not very suitable for use as small office firewall or in home.
